Note to other teachers and users of these slides. Andrew would be delighted if you found this source material useful in giving your own lectures. Feel free to use these slides verbatim, or to modify them to fit your own needs. PowerPoint originals are available. If you make use of a significant portion of these slides in your own lecture, please include this message, or the following link to the source repository of Andrew's tutorials: http://www.cs.cmu.edu/~awm/tutorials. Comments and corrections gratefully received.

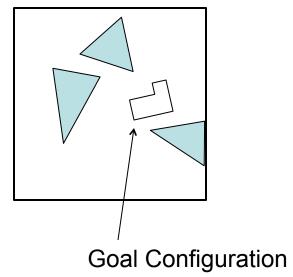

Let's Think About Automating Reasoning

- We've already seen
 - Reasoning with Constraints
 - State space search in discrete spaces
 - Reasoning with multiple agents
- Later (in this course) we'll see
 - Probabilistic Reasoning with Markov Decision
 Processes, Reinforcement Learning and HMMS
- But NOW let's think about

SPATIAL REASONING

Spatial Reasoning

Can't we use our previous methods?

Discrete Search? – Not a discrete problem

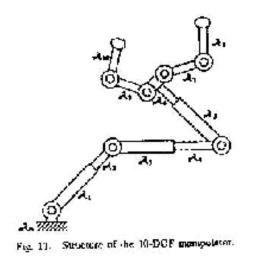

CSP? – Not a natural CSP formulation

Probabilistic? – Nope.

Robots

For our purposes, a robot is:

A set of moving rigid objects called <u>LINKS</u> which are connected by <u>JOINTS</u>.

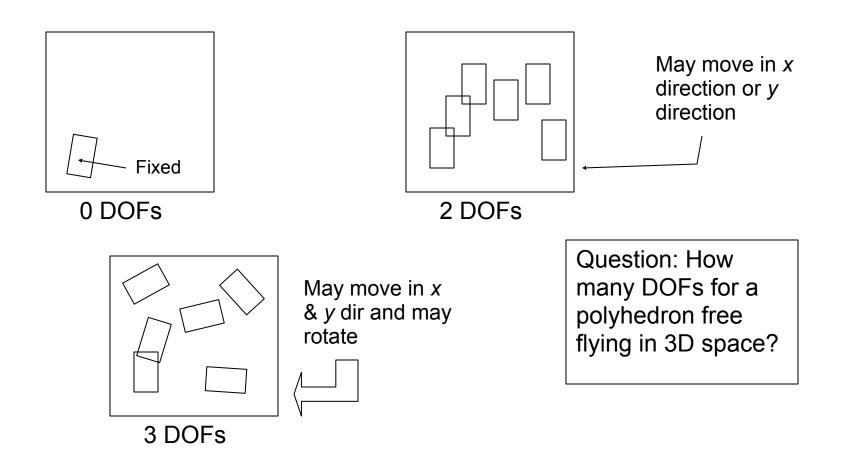

Typically, joints are REVOLUTE or PRISMATIC.

Such joints each give one DEGREE OF FREEDOM.

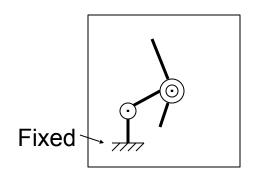

Given p DOFs, the configuration of the robot can be represented by p values $\mathbf{q} = (q_1 \ q_2 \cdots \ q_p)$ where q_i is the angle or length of the ith joint

Free-Flying Polygons

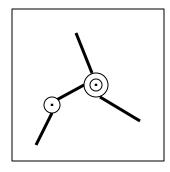

If part of the robot is fixed in the world, the joints are all the DOFs you're getting. But if the robot can be free-flying we get more DOFs.

Examples

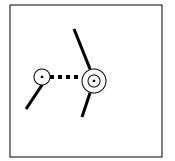

How many DOFs?

Free flying

How many DOFs?

Midline ■■■ must always be horizontal.

How many DOFs?

The configuration q has one real valued entry per DOF.

Robot Motion Planning

An important, interesting, spatial reasoning problem.

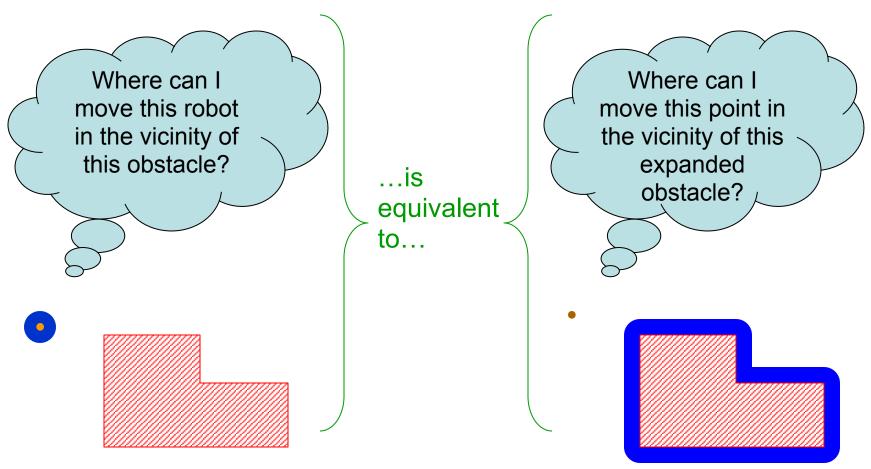

- Let A be a robot with p degrees of freedom, living in a 2-D or 3-D world.
- Let B be a set of obstacles in this 2-D or 3-D world.
- Call a configuration LEGAL if it neither intersects any obstacles nor self-intersects.
- Given an initial configuration $q_{\rm start}$ and a goal config $q_{\rm goal}$, generate a continuous path of legal configurations between them, or report failure if no such path exists.

Configuration Space

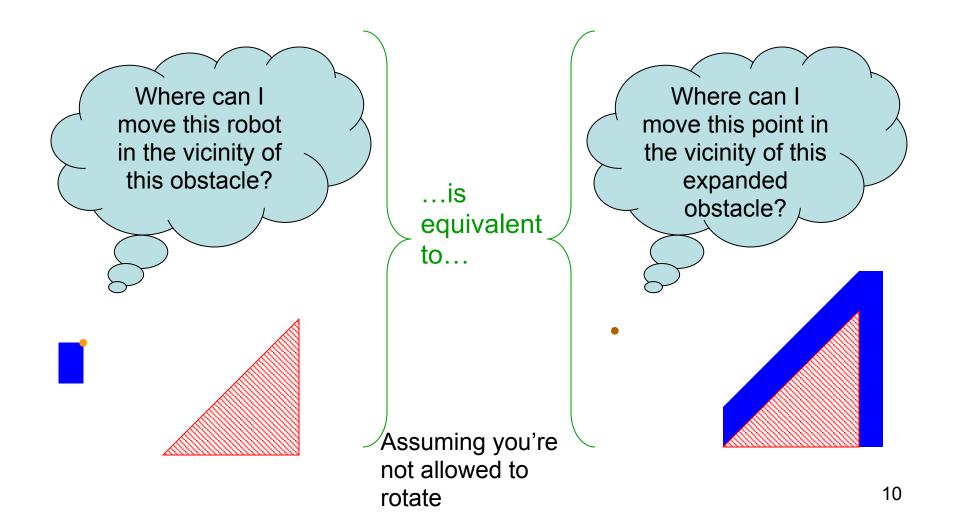

Is the set of legal configurations of the robot. It also defines the topology of continuous motions

For rigid-object robots (no joints) there exists a transformation to the robot and obstacles that turns the robot into a single point. The C-Space Transform

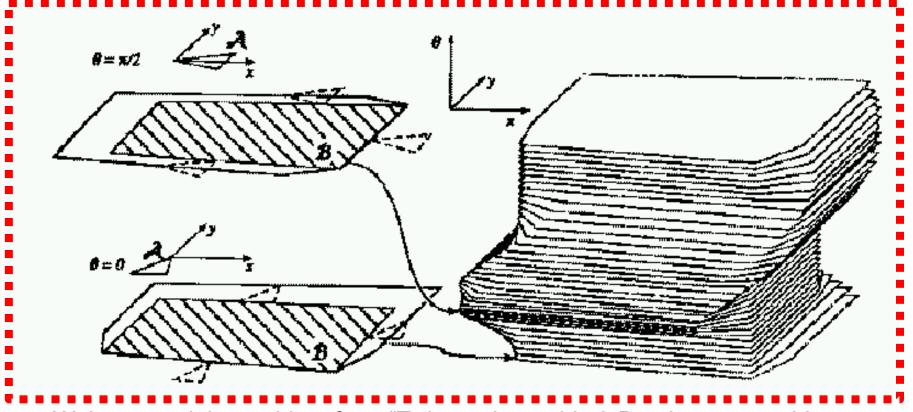

Configuration Space Transform Examples 2-D World 2 DOFs

Configuration Space Transform Examples 2-D World 2 DOFs

Configuration Space Transform Examples

We've turned the problem from "Twist and turn this 2-D polygon past this other 2-D polygon" into "Find a path for this point in 3-D space past this weird 3-D obstacle".

Why's this transform useful?

Because we can plan paths for points instead of polyhedra/polygons

Warning: Topology

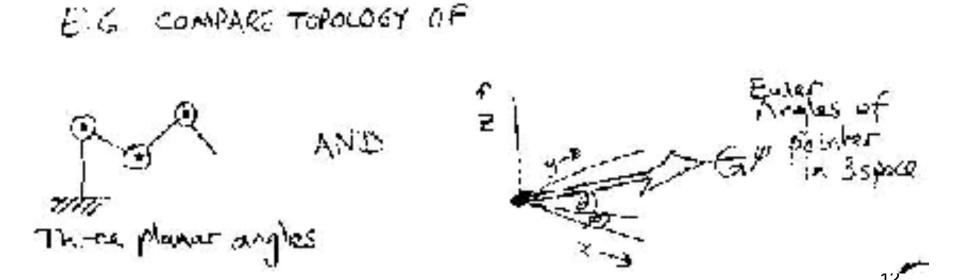

If you ever tried implementing these things you'll quickly start having to deal with spaces which aren't \Re^N .

E.G. The space of directions in 2-D space: SO(2).

AND The space of directions and orientations in 3-D space: SO(3).

AND Cartesian products thereof.

NOT JUST A CASE OF: "So what? Some of my real numbers happen to be angles".

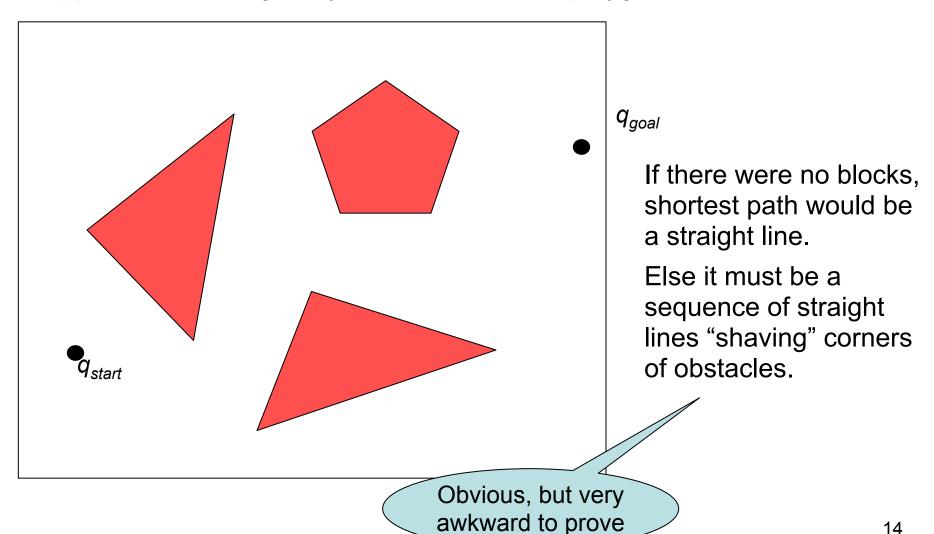

Robot Motion Planning Research

... Has produced four kinds of algorithms. The first is the Visibility Graph.

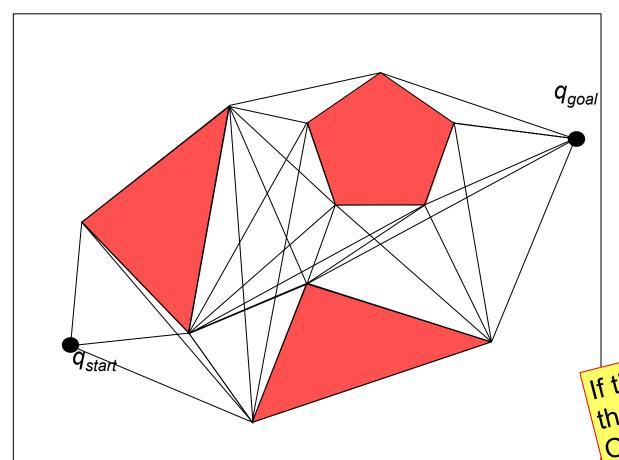

Visibility Graph

Suppose someone gives you a CSPACE with polygonal obstacles

14

Visibility Graph Algorithm

- Find all non-blocked lines between polygon vertices, start and goal.
- Search the graph of these lines for the shortest path. (Guess best search algorithm?)

If there are n vertices, the easy algorithm is O(n³). Slightly tougher O(n²logn). O(n²) in

theory.

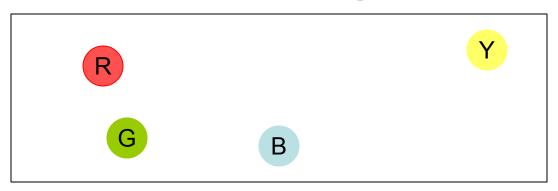

Visibility Graph Method COMPLAINT

- Visibility graph method finds the shortest path.
- Bit it does so by skirting along and close to obstacles.
- Any error in control, or model of obstacle locations, and Bang! Screech!!

Who cares about optimality?

Perhaps we want to get a non-stupid path that steers as far from the obstacles as it can.

Voronoi Diagrams

Someone gives you some dots. Each dot is a different color.

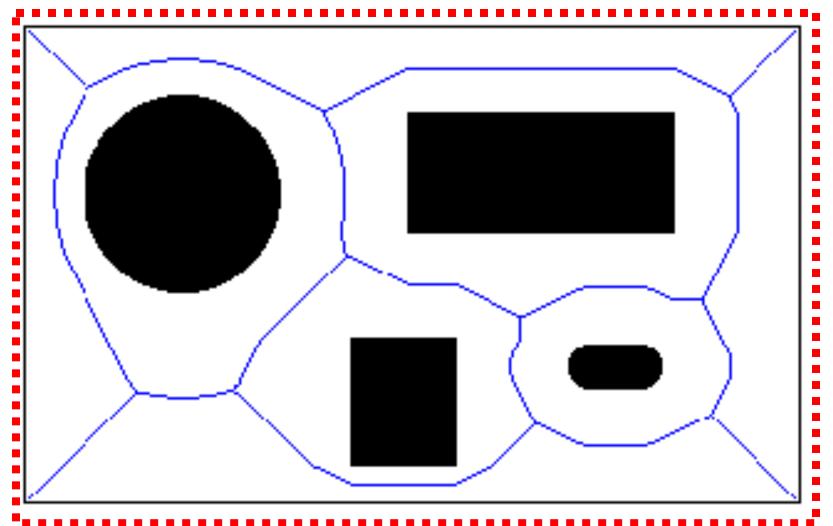

You color in the whole of 2-D space according to this rule:

"The color of any given point equals the color of the nearest dot."

The borders between your different regions are a VORNOI DIAGRAM.

For n point in 2-D space the exact Voronoi diagram can be computed in time $O(n \log n)$.

Voronoi Diagram from Polygons instead of Points

Voronoi Diagram Methods for C-Space Motion Planning

- Compute the Voronoi Diagram of C-space.
- Compute shortest straightline path from start to any point on Voronoi Diagram.
- Compute shortest straightline path from goal to any point on Voronoi Diagram.
- Compute shortest path from start to goal along Voronoi Diagram.

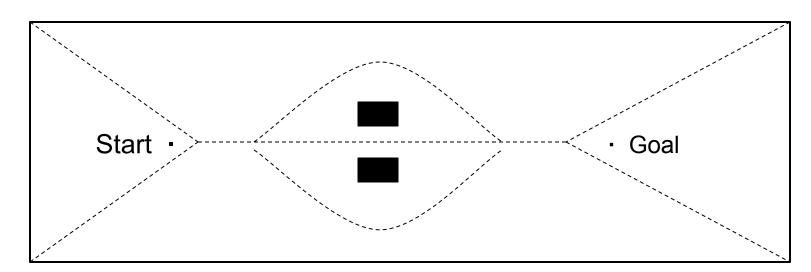

- Assumes polygons, and very complex above 2-D.
 - Answer: very nifty approximate algorithms (see Howie Choset's work http://voronoi.sbp.ri.cmu.edu/~choset)
- This "use Voronoi to keep clear of obstacles" is just a heuristic. And can be made to look stupid:

Can you see how?

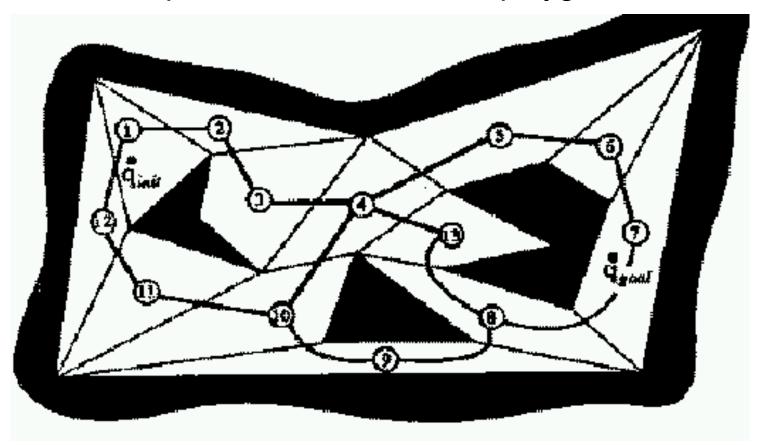

- Assumes polygons, and very complex above 2-D.
 - Answer: very nifty approximate algorithms (see Howie Choset's work http://voronoi.sbp.ri.cmu.edu/~choset)
- This "use Voronoi to keep clear of obstacles" is just a heuristic. And can be made to look stupid:

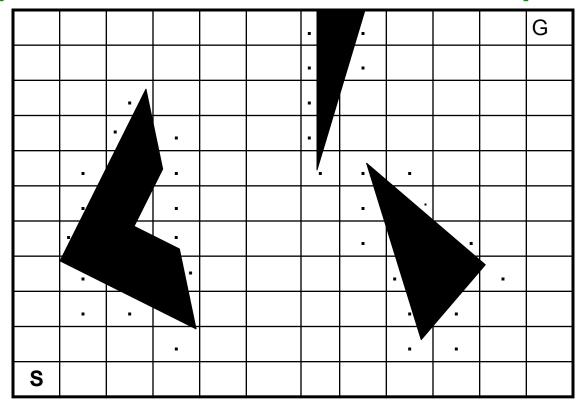

Cell Decomposition Methods

Cell Decomp Method One: Exact Decomp

Break free space into convex exact polygons.

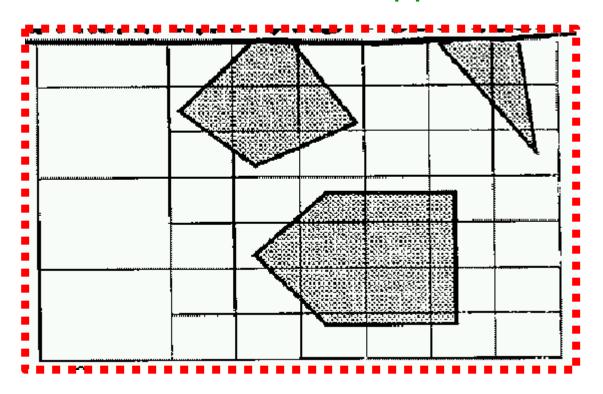

Approximate Cell Decomposition

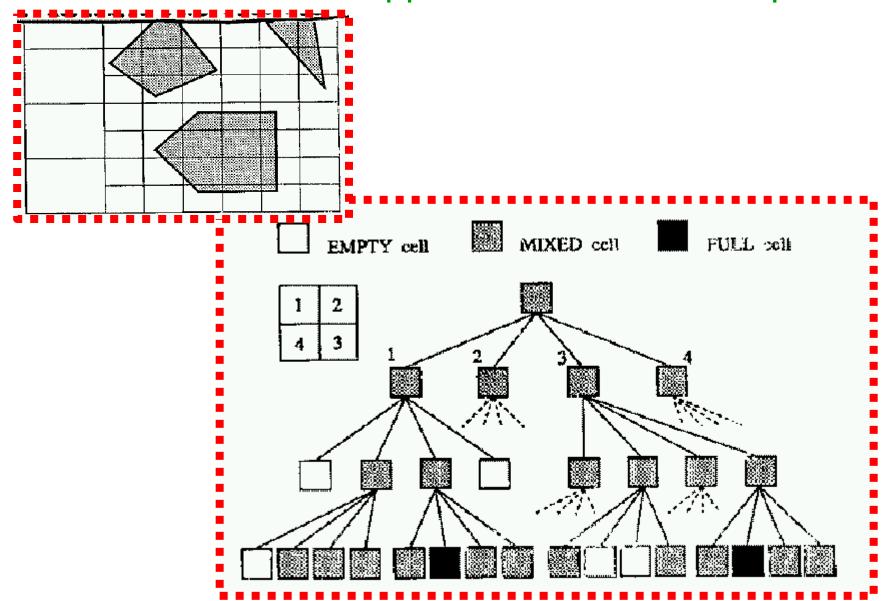

- Lay down a grid
- Avoid any cell which intersects an obstacle
- Plan shortest path through other cells (e.g. with A*)
 If no path exists, double the resolution and try again. Keep trying!!

Variable Resolution "Approximate and Decompose"

Variable Resolution "Approximate and Decompose"

Approximate Cell Decompanies tion

□ Not so many complaints. This is actually used in practical systems.

But

- Not exact (no notion of "best" path)
- Not complete: doesn't know if problem actually unsolvable
- o Still hopeless above a small number of dimensions?

Potential Methods

Define a function $u\begin{pmatrix} q \\ {}^{\sim} \end{pmatrix}$

u: Configurations $\rightarrow \Re$

Such that

 $u \rightarrow \text{huge}$ as you move towards an obstacle

 $u \rightarrow \text{small}$ as you move towards the goal

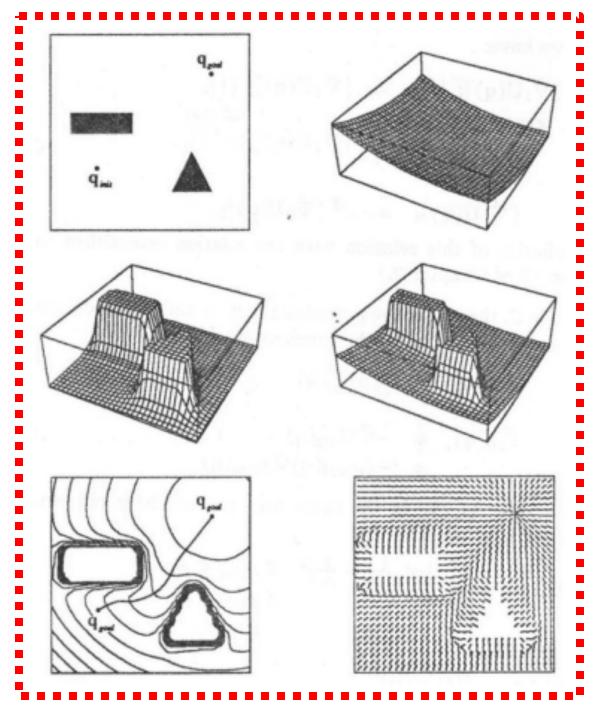

Write $d_g(q) = \text{distance from } q \text{ to } q \text{ goal}$ $d_i(q) = \text{distance from } q \text{ to nearest obstacle}$

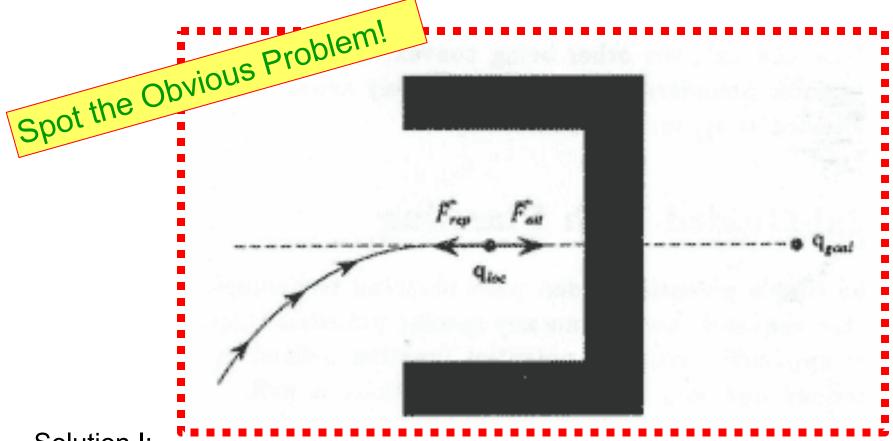

One definition of $u: u(q) = d_i(q) - d_g(q)$

Preferred definition: $u(q) = \frac{1}{2} \sum_{i} \left(d_g(q) \right)^2 + \frac{1}{2} \eta \frac{1}{d_i(q)^2}$

SIMPLE MOTION
PLANNER: Steepest
Descent on *u*

Potential Field Example

Solution I:

Use special local-minimum-free potential fields (Laplace equations can do this) – But very expensive to compute

Solution II:

When at a local minimum start doing some searching - example soon

Comparison

	Potential Fields	Approx Cell Decomp	Voronoi	Visibility
Practical above 2 or 3 D?				
Practical above 8 D?				
Fast to Compute?				
Usable Online?				
Gives Optimal?				
Spots Impossibilities?				
Easy to Implement?				

And now.....

Let's look at one of the state-of-the-art motion planners.

Latombe's Numerical Potential Field Method

- Combines Cell Decomposition and Potential Fields
- Key insight: Compute an "optimal" potential field in world coordinate space (not config space)
- Define a C-space potential field in terms of worldspace potential field.

N.P.F. Step I

Get given a problem.

You have a world ω which is a 2-D or 3-D space.

There are obstacles and a robot.

Robot may be fixed or free-flying, may be jointed or totally rigid.

You have a start configuration.

Goal spec. is more flexible than mere goal configuration: You can specify between 1 and *P* points (*P* = number of DOFs) in world space, and state that various points on the robot should meet those world points. E.G.

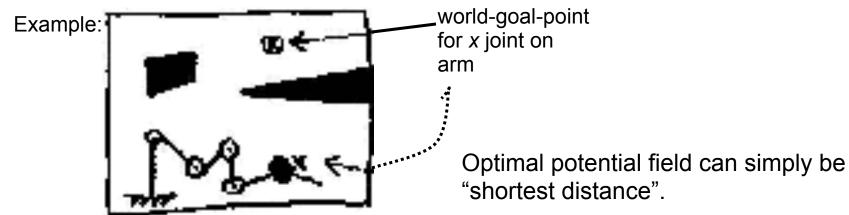

"I want my tip to end up here"

or

"I want my tip here, my wrist there, and my shoulder way over there."

N.P.F. Step II

For each given world-goal-point we compute an optimal potential field in worldspace.

Computed by discretizing world-space on a fine grid.

Q: Why is fine grid not too expensive now?

Skeletons in the World Space

Fig. 4. Standarder of weats, are akeletons.

Easy to skeletonize with a grid

Then what?

- Extend the skeleton to join to the goal
- 2. Compute least-cost-to-goal for all points on skeleton
- 3. Define potential field by traveling downhill to local part of skeleton.

The exact definition of this is unclear. It is NOT "shortest path to skeleton" and not "shortest path to goal" but a kind of combination. Defined inductively by first de**** all points 1 away from skeleton as 1 + least adjacent skeleton-cell cost. Then points next to them, etc., etc.

Potential from the Skeleton Method

File 6 Common et impresso Wernlental.

Remember, we do one of these for each world-goal-point.

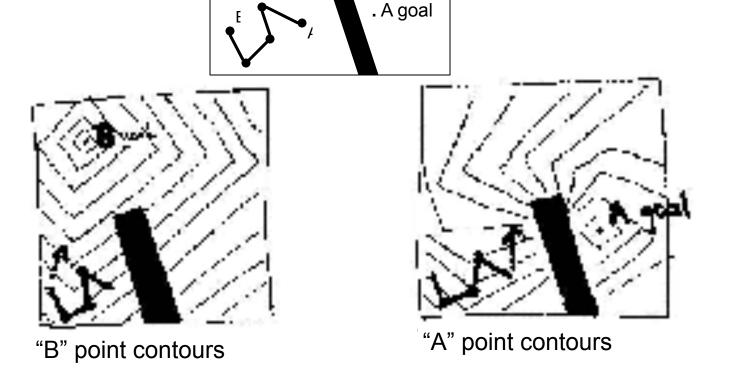

N.P.F. IV

Compute a potential field for configurations.

Remember, for each goal point we have computed a world-

. B goal

space potential.

N.P.F. IV

Combining world space potentials into a C-space potential. If $W_i(point_i(q))$ is the potential field for the i'th distinguished point on the robot...

We could define

$$\mu\left(q\right) = \sum_{i.e.distinguished} W_i\left(\text{point}_i\left(q\right)\right)$$

or many other combination methods, e.g.

$$\mu\left(q\right) = \max_{i.e.distinguished} W_i\left(\operatorname{point}_i\left(q\right)\right)$$
Empirically, this is preferred

NPF V

Perform gradient descent from the start configuration with your C-space potential field...

Until...

- You get to the goal config
- You find you're in a local minimum.

Sadly, although the worldspace potentials were minimum-free, the combination is not.

What to do in a local minimum??

- 1. Best first search
- 2. Random search

Best First Search with NPF

- Remember all the C-space places you've visited in the search (search on a fine Cspace grid).
- When you expand a grid point consider all its neighbors on the grid.
- Always expand gridpoint with lowest Cspace potential value.
 - During most of search runs quickly down gradient.
 - When in a local minimum, must wait for minimum to "fill up".

Empirical Results

1/10 second to solve on a SPARC. (In 1992 claimed to be fastest algorithm by 2 orders of magnitude, and three orders of nuns.)

5 seconds to solve.

3 degrees of freedom.

Randomized Search with NPF

- On each step choose from a random set of, say, 100 neighbors on C-space grid.
- If none reduce the potential, current state is recorded as being a local minimum.
 - If was local minimum, perform a random walk for *t* timesteps to escape (one hopes)
- Keep doing this, building up a graph of "adjacent" local minima.
- Continue until one local minimum turns out to be the goal.

HOW? Many details, and a slightly depressingly large number of magic parameters are involved.

Randomized Search Results

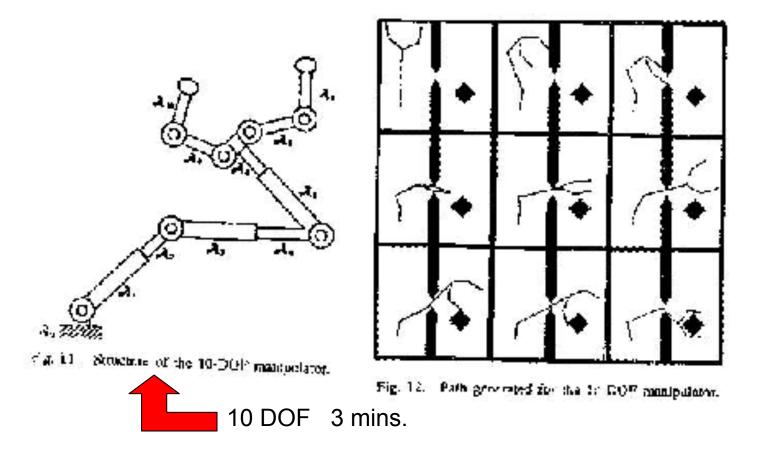

10 secs. (Slower than best first)

2 mins. 8 DOF

Spectacular result.

Randomized Search Results

31 DOF manipulator in 3-D workspace 15 mins.

What Should You Know

- How to define configuration space obstacles
- The basic idea behind, and Pros and Cons of
 - > VISIBILITY GRAPH METHODS
 - > VORONOI METHODS
 - > CELL DECOMPOSITION METHODS
 - >> POTENTIAL FIELD METHODS
- Latombe's trick of using optimal world-space potentials for good C-space potentials.

See also the book <u>Robot Motion Planning</u> by Latombe (Klumer 1990). Russell & Norvig has a rather brief chapter on the subject.
